⑯ Power delivery circuit with current sensing.

⑯ A power delivery circuit for supplying load current to a load includes a current switch connected on the high potential side of a load. In order to detect a current condition, such as an over-current condition in the load, a current sensing and detection circuit preferably cooperates with the current switch wherein such switch comprises a multicellular device with a plurality of terminals. Such terminals include a first main current terminal connected to a source of high potential, a second main current terminal connecting a majority of device cells to the load, a first auxiliary terminal connected at one end to a minority of device cells so as to provide a current generally proportional to the main device current, and a second auxiliary terminal connected at one end to a majority of device cells. The current detection circuit preferably comprises one branch connected between the first auxiliary terminal and ground and

including, in serial circuit, a current-to-voltage converting resistor providing a voltage at one end approximately proportional to the main device current and a bias signal-controlled transimpedance device, and another branch connected between the second auxiliary terminal and ground and providing a bias signal for the transimpedance device in the first branch. In another embodiment, the first branch includes at least two transistors and a resistor serially connected between a current sense terminal of the MOSFET and a reference potential. The second branch also includes at least two serially connected transistors connected between a terminal of the MOSFET and the reference potential. The transistors are cross-connected between branches and provide an inverted current mirror and a current mirror. Fifth and sixth transistors may also be included as part of the current sensing circuit.

EP 0 397 102 A2

FIG.1

Power Delivery Circuit With Current Sensing

Technical Field

The invention relates generally to current sensing circuitry and more particularly to current sensing circuitry in combination with a current controlling device in a power delivery circuit, especially of the high-side switch type. The invention even more particularly relates to a current sensing circuit useful for detecting over-current conditions in "H"-bridge-type power delivery circuits for bidirectional motors and in which the current controlling devices are provided by current sensing semiconductors.

Background Art

The advent of solid state power drivers has created the need to monitor or to sense load current for device protection and other functions. The power delivery circuits for supplying load current to a load and which further include current sensing capabilities are generally known and are of diverse types. In U.S. patent 4,654,568 to Mansmann, there is disclosed an H-bridge switch circuit for a load such as a motor. More specifically, the various switches of the H-bridge are MOSFET semiconductors, with two of those MOSFETs comprising current sensing MOSFETs. In that described embodiment, the current sensing MOSFETs are connected in the "low" side of the power delivery circuit to the motor. The current sensing MOSFETs are multi-cellular devices in which a major current-carrying cellular portion consists of a large number of cells connected in parallel for carrying the main load current and in which a minor current-carrying cellular portion consists of a relatively small number of cells substantially in parallel therewith and having a separate terminal for carrying a current proportional to that load current. That separate terminal is termed the "current sensing" terminal and may be useful for developing a signal indicative of the major current carried by the current sensing MOSFET.

In U.S. 4,654,568, the current conducted via the current sensing terminal is developed as a voltage level which is applied to an input of an operational amplifier for amplification and subsequent evaluation. The current sensing circuit which converts the current carried at the current sensing terminal to a corresponding voltage level appears in the patent as at least one sensing resistor operatively connected between the current sensing terminal and ground. The operational amplifier is connected to the current sense terminal and amplifies the voltage developed across that resistor (sense

voltage). Sensing current in this manner inherently induces errors in the ratioing of the majority current and the sensing current in the current sense MOSFET. More significantly, as the temperature of the current sense MOSFET increases, as under increasing load conditions, the aforementioned induced error percentage and likewise associated sense voltage error percentage increases.

Furthermore, for safety reasons required in automotive applications, power switch protection and current sensing need to be implemented in a "high side" configuration. This configuration places the current switch or power switch in between the positive supply and the load. If the current sensing method demonstrated in U.S. 4,654,568 were to be used in a high side configuration, it would have all of the previously described problems. Further, the operational amplifier supply voltage would have to be higher than the sum of the current sense terminal voltage and the amplified voltage drop across the sensing resistor. Since the voltage drops across the current sense MOSFETs (power MOSFETs) are very low, this would require an operational amplifier voltage supply to be higher than the voltage supply connected to the current sense MOSFET, which is typically the battery, V_{BATT} , in automotive applications. This method is further complicated by requiring the threshold reference voltage, which needs to be generated and used for comparing the amplified resistor voltage drop to some threshold for protection, to be operatively referenced above the current sense terminal potential, which is changing with varying load conditions and battery voltage.

Alternatively, an operational amplifier could be connected in a current amplifier configuration, sometimes called a virtual ground reference, instead of a voltage amplifier configuration. This would require the operational amplifier to have a high common mode input voltage nearly equal to the supply voltage, a threshold reference voltage to be operatively referenced below the current sense terminal potential which is changing with varying load conditions and battery voltage, and would require an operational amplifier to work at the high voltage transients that are present in automotive applications (typically filtered to 45 volts).

Disclosure of the Invention

It is an object of the invention to provide a power delivery circuit having a switch located on a high potential side of the load and including simple and reliable circuit means to sense a current con-

dition, such as an over-current condition in the load. The power delivery circuit may include means to turn off the current through the switch upon detection of an over-current condition to prevent destruction of the switch or of the load. The foregoing type of circuit is particularly suitable for use with a single-polarity voltage supply, such as typically provided in automobiles.

Another object of the invention is the provision of simple and reliable circuit means to sense the condition of current through a current switch to a load and which functions accurately within a relatively narrow tolerance range and over a relatively broad operating range.

A further object of the invention is to provide a power delivery circuit with over-current protection that functions accurately and reliably despite large changes in ambient temperature, such as is typically encountered in an automobile.

Another object of the invention is to provide a power delivery circuit with over-current protection that can be inexpensively manufactured with the use of readily-available discrete components.

Another object of the invention is to provide an improved current sensing circuit for use in conjunction with a current controlling device such as a current sensing MOSFET, connected to respective ones of two auxiliary terminals associated with the current sensing MOSFET. Included within the object is the provision of such current sensing circuit having a constant load current (I_L)-to-voltage sense (V_s) conversion ratio which is independent of variations in the supply potential and in the load current.

It is a further object of the invention to provide a current sensing circuit of the type described which is particularly suited for use with a current sensing device or switch in a "high side" configuration and which exhibits improved accuracy.

It is a still further object of the invention to provide a current sensing circuit of the type described in which such improvements in accuracy and stability are obtained with a concomitant minimization of cost and complexity associated with the number of resistors required.

In accordance with a preferred form of the invention, the power delivery circuit for supplying load current to a load is provided. The circuit includes a power node for connection to a source of electrical power, a load node for connection to a load, and a high potential current path for supplying electrical current from the power node to the load node. The high potential current path includes a current switch whose switching state is controlled by a control signal on an associated control terminal. The power delivery circuit further includes current sensing circuitry for reliably sensing the level of load current over a wide operating range. The

power delivery circuit may further include a single, highly reliable over-current detection circuit responsive to the sensed condition of current in the high potential current path. The over-current detection circuit is for detecting when the current in the high potential current path exceeds a predetermined level. The power delivery circuit, preferably, further includes current turn-off means for disabling current flow to the load when an over-current condition is detected.

In a preferred embodiment of the invention for providing accurate and reliable over-current detection, the current switch in the high potential current path comprises a multicellular device with a plurality of terminals including a first main current terminal connected to the power means, a second main current terminal connecting a majority of device cells to the electrical load, a first auxiliary terminal connected at one end to a minority of device cells so as to provide a current generally proportional to the main device current, and a second auxiliary terminal connected at one end to the majority of device cells. The over-current detection circuit in this embodiment preferably comprises one branch connected between the first auxiliary terminal and a reference potential such as ground and including, in serial circuit, a bias-controlled transimpedance device such as a transistor and a resistor placed between the transimpedance device and the ground and providing a voltage at one end approximately proportional to the main device current, and another branch connected between the second auxiliary terminal and the ground and providing a control signal for the transimpedance device in the first branch.

The transimpedance device in the foregoing over-current detection circuit beneficially couples the current from the high-potential-side first auxiliary node to the resistor that is at low potential. This permits such resistor to be selected so as to provide a desired sense voltage indicative of a particular load current. Moreover, the branch connected between the second auxiliary terminal and the ground for providing the control signal preferably includes a transistor having its base cross-connected to the transimpedance device in the first branch and further having its base shorted to its collector.

A further improved current sensing circuit is provided which has particular utility in power delivery circuits in which the current controlling device is in the "high side", and especially in the high side of an H-bridge switch arrangement. The further improved current sensing circuit includes first and second branches each connected at one end to a respective one of the first and second auxiliary terminals and includes means for connection in common at the other end to a reference potential in

the power delivery circuit. More specifically, the current sensing circuit comprises the first branch including first and third series-connected semiconductor devices, such as transistors; the second branch including second and fourth series-connected semiconductor devices, such as transistors; the first and fourth semiconductor devices each being controlled by bias signals and acting in a transimpedance mode of operation; the second and third semiconductor devices being cross-connected with the first and fourth semiconductor devices respectively to provide the respective bias signals thereto; and the first branch further including impedance means, such as a resistor, connected in series circuit therewith for providing a voltage at a node at one end of the impedance means approximately proportional to the main device current, that node being connectable to a detection circuit.

In accordance with an embodiment of the invention, the first, second, third and fourth semiconductor devices comprise respective bipolar transistors, and the first and second transistors are of one conductivity type and the third and fourth transistors are of the opposite conductivity type. Further, the first main current terminal of the current controlling device is adapted to be connected to one polarity of a source of power having relatively opposite polarities, the second main current terminal of the current controlling device is adapted to be connected to one side of a load, and the other side of the load is adapted to be connected to the other polarity of the source of power. The current controlling device with the current sensing capability is preferably connected in the "high side" of the power delivery circuit such that it is relatively more positive than the load. Both the first and the second transistors are PNP transistors and the third and fourth transistors are NPN transistors. The reference potential in the power delivery circuit, to which the first and second branches of the sensing circuit are adapted to be connected in common, is the other polarity of the source of power, and is typically ground.

The betas (β) of the first and second transistors are substantially identical and the betas of the third and fourth transistors are substantially identical.

Further in accordance with the invention, the second and third transistors are each connected in respective shorted base-to-collector configurations and the base of the second transistor is connected to the base of the first transistor and the base of the third transistor is connected to the base of the fourth transistor. The impedance means in the first branch is a first resistor. In one embodiment, the second branch circuit includes a respective second resistor in series circuit therewith. In an alternate embodiment, a single resistor is connected in com-

mon in the first and the second branches and is connected to the reference potential.

In a further embodiment, still further improvement in performance of the current sensing circuit 5 may be realized through the addition of fifth and sixth transistors thereto as an alternative to or modification of the shorted base-to-collector connections. The circuit becomes less sensitive to beta variations, and thus temperature, in the other four transistors.

In a still further embodiment, fifth and sixth transistors are added to the current sensing circuit, a respective one being serially connected in each of the branches intermediate the other transistors. 15 The respective fifth and sixth transistors provide the major voltage drops thereacross to minimize the voltage across the other transistors and thereby minimize variations in the betas of those other four transistors despite variations in the supply voltage.

Best Modes for Carrying out The Invention

In the drawings, like reference numerals refer to like parts unless otherwise noted.

Fig. 1 shows a general overview of the power delivery circuit, and the current detection circuit of the invention as used in conjunction with an exemplary H-bridge circuit 10. The power delivery circuit of Fig. 1 additionally includes control circuitry 12 associated with H-bridge circuit 10.

Considering first H-bridge circuit 10, a load leg L_0 extends horizontally and contains a load 14, such as an electrical motor. Vertical leg L_1 extends between left end node 16 of load leg L_0 and an upper node 18, which typically is at a nominal 12-volt potential for automotive applications. Load leg L_2 extends between node 16 and a node 20, typically at ground reference potential. Connected between a right end node 22 of load leg L_0 and an upper node 18' is load leg L_3 . Load leg L_4 is connected between end node 22 and ground node 20'.

The reference to "vertical" and "horizontal" orientations of the various legs of H-bridge circuit 10 are, of course, merely for descriptive purposes and may or may not accurately describe the layout of an actual H-bridge circuit.

As indicated by the phantom lines high potential nodes 18 and 18' are typically interconnected, and ground nodes 20 and 20' similarly are also interconnected.

Contained within load legs L_1 to L_4 , respectively, are current switches S_1 to S_4 , respectively. These switches are controlled by respective signals on their gates G_1 to G_4 . As used herein, the term "gate" broadly encompasses any form of control lead for changing the switching state of a current switch. As such, the term "gate" is intended to be synonymous with the "base" of a bipolar transistor, for example.

In order to direct current through load 14 in the direction shown by a curved arrow 25, appropriate signals are placed on gates G_1 and G_4 of switches S_1 and S_4 , respectively, to turn such switches on, while appropriate signals are placed on the gates G_2 and G_3 of switches S_2 and S_3 , respectively, to keep these switches off during this time. Conversely, to direct current through load 14 in the direction shown by curved arrow 27, switches S_2 and S_3 are made to conduct by appropriate control of their gates, while the other switches S_1 and S_4

are kept off during this time.

In order to prevent an over-current condition from destroying the load 14 or the switches S_1 and S_3 located in the high potential legs of H-bridge circuit 10 ("high side switches"), over-current detectors 24 and 30, shown as part of control circuitry 12, respond to electrical conditions in high potential legs L_1 and L_3 , respectively. In a preferred arrangement, over-current detector 24 is responsive to electrical conditions within switch S_1 , described below in connection with Figs. 2A and 3.

Continuing with Fig. 1, if an over-current condition is detected by detector 24, a gate override circuit 26 overrides a conventional gate control function 28 to assure that switches S_1 and S_4 remain off. Similarly, upon detection of an over-current condition in switch S_3 by detector 30, a gate override circuit 32 prevents conventional gate control function 34 from turning on switches S_2 and S_3 .

Switch S_1 and over-current detector 24 are described in greater detail in Fig. 2A. Switch S_3 and over-current detector 30 are suitably of corresponding construction to switch S_1 and detector 24. Turning to Fig. 2A, switch S_1 is represented by a symbol for a MOSFET device, such as that sold by International Rectifier under the trademark "HEXSense". The main load terminals of HEXSense device S_1 are illustrated as terminals 16 and 18. Terminal 16 is the main source terminal of switch S_1 , and terminal 18 is the sole drain terminal of the switch. Gate G_1 corresponds to gate G_1 of current switch S_1 of Fig. 1.

HEXSense device S_1 includes two auxiliary, further terminals 40 and 42. The interrelation of auxiliary terminals 40 and 42 to the main terminals 16 and 18 of switch S_1 is explained in connection with the schematic representation of switch S_1 in Fig. 3. Cells C_1 through C_n shown in Fig. 3, represent individual cells of HEXSense device S_1 . Common gate G_1 provides a common gate signal for the individual gates of cells C_1 - C_n . Drain electrode 18 serves as a common drain electrode for all the cells C_1 - C_n . Source terminal 16 serves as a common source for a majority of the cells of switch S_1 , namely cells C_3 - C_n , while terminal 42 (generally referred to as the Kelvin terminal, K) serves as an auxiliary source electrode connected in common with source electrode 16 except for minor metallization resistance (not shown). Auxiliary terminal 40 (sometimes designated "C.S." for current sensing electrode) serves as a source electrode for only a minority of the cells of switch S_1 , namely cells C_1 - C_2 . In an actual device having several thousands or more cells, the auxiliary terminal 40 could serve as a source for perhaps several hundreds of cells.

HEXSense device S_1 is formed as one integrated circuit with each of its cells having similar

characteristics to its other cells. For this reasons, a current which flows from drain 18 to auxiliary source 40 is approximately proportional to the current that flows from drain 18 to main source 16, where such proportion is determined by the ratio of the minority number of cells connected to terminal 49 to the majority number of cells connected to terminal 16.

Further details of HEXSense device S_1 are contained in Power MOSFET Application Notes, No. AN-959, published by International Rectifier in 1986, and incorporated herein by reference.

In view of the above description of the multicellular construction, it will be apparent to those skilled in the art that other types of multicellular switching devices could be used herein instead of a HEXSense device. By way of example, a multicellular thyristor device would comprise a suitable replacement.

Returning to Fig. 2A, auxiliary terminals 40 and 42 are shown connected to a current-sensing circuit 43 having two branches and comprising PNP bipolar transistors 44 and 46 and resistors 48 and 50. Current from S_1 that flows through auxiliary terminal 40 is conducted in one branch through a bias-signal controlled transistor 44 to cause a voltage drop across resistor 48. Transistor 44 and resistor 48 are series connected in the one branch, with the transistor connected to auxiliary terminal 40 and the resistor having one end connected to ground in the illustrated embodiment. Neglecting the bias signal, or base current, in transistor 44, the voltage drop across resistor 48 is proportional to the current flowing through terminal 40 and, hence, to the load current flowing through terminal 16. The voltage at node 52 is thus proportional to the load current. Transistor 44 functions as a transimpedance device to couple the current from the high potential side auxiliary node 40 to the low potential side resistor 48. This permits resistor 48 to be selected so as to provide a desired sense voltage indicative of a particular load current.

In the other branch, transistor 46 of circuit 43, having a short across its base and collector so as to function as a P-N diode, provides a bias signal (base current here) for transistor 44. Transistor 46 and resistor 50 are series connected in that other branch, with the transistor connected to auxiliary terminal 42 and the resistor connected between the transistor's collector and ground.

For optimized performance, it is preferred that the transistors 44 and 46 be formed of matched silicon and that the base currents of those transistors be substantially the same. In this manner, the voltage drops across the emitter-base junctions of transistors 44 and 46 are nearly equal. Thus, the sensing circuit 43 forms an impedance matching buffer and will maintain the same voltage at terminal 40 as the voltage at terminal 42. It should be appreciated that this is a critical requirement to maintain the current ratio accuracy of the HEXsense device. Small deviations in the voltage between terminals 40 and 42 create large errors in the current ratio of the HEXsense device.

Resistors 48 and 50 of the current-sensing circuit 43 are preferably, but not necessarily, selected to result in equal currents through them when an over-current condition occurs in the load. Resistors 48 and 50 may be selected so that the voltage at node 52 varies somewhat linearly with the load current about a particular value of load current according to the ratio of the number of cells in HEXSense switch S_1 connected to auxiliary terminal 40 to the number of cells in such switch connected to load 14. A circuit designer can, however, select resistors 48 and 50 so that the voltage at node 52 varies as above with load current but according to a ratio differing from the foregoing ratio. Thus, a circuit designer can select resistors 48 and 50 to alter the relative change of voltage at node 52 to the change of level of current in load 14.

Where the line voltage on node 18 (Fig. 2A) is nominally 12 volts, PNP transistor 44 and 46 typically each have a beta value of 200 and a breakdown voltage of 60 volts, and resistors 48 and 50 typically have values of 487 and 9.1K ohms, respectively. Additionally, a 0.001 or 0.01 microfarad capacitor 49 (shown in phantom) is preferably placed across resistor 48 to filter any potential current spikes during turn-on.

The above-described arrangement of current-sensing circuit 43 is relatively accurate and stable, being well-suited to provide a voltage at node 52 which is proportional, within a tolerance of about $\pm 3\%$, to the actual current through the associated current switch (and load) in the region of a particular value of load current across a relatively broad range of operating characteristics, as often encountered in, for example, an automotive environment. That operating range across which this circuit configuration is accurate to within $\pm 3\%$ includes variations of $\pm 25\%$ in the supply potential from the nominal 12 volts, variations in the gains (β) of transistors 44 and 46 in the range of 100 to 500, or more and/or variations in temperature of $\pm 60^\circ C$ from an ambient of about $25^\circ C$. Such variations in the supply potential are occasioned by inductive loading on the battery supply and/or dissipation via age and/or loading. Variations in the transistor gains (β) occur through initial mismatch and particularly as operating temperatures change, with lower gains (i.e., 100 or less) being at relatively cold ambient temperatures and the higher gains (i.e., 500 or more) being at hot operating temperatures.

The voltage on node 52 of current-sensing circuit 43 may serve as an input to a variety of "use" devices, and in the described embodiment it is applied to input node 60 of a comparator 62, whose other input is a reference voltage level 64 selected to determine the over-current level. The output of comparator 62 is then processed by a 12-volt-to-5-volt level shifter 66 so that further processing can conveniently occur with standard 5-volt logic circuitry. When the voltage at node 60 exceeds that of reference level voltage 64, the comparator 62 provides an output, processed by voltage level shifter 66, which is applied to gate override circuit 26 described in connection with Figs. 1 and 4.

Current-sensing circuit 43 can be replaced by other circuits that provide a voltage at node 60 of comparator 62 that is approximately proportional to load current, with possibly greater or lesser accuracy and greater or lesser cost.

An alternative current-sensing circuit is illustrated in Fig. 2B as circuit 70. Like circuit 43 of Fig. 2A, circuit 70 of Fig. 2B preferably includes two PNP bipolar transistors 44 and 46 and resistors 48 and 50. Transistor 44 and resistor 48 of circuit 70 function in the same manner as the like-numbered elements of circuit 43 of Fig. 2A. An additional PNP bipolar transistor 72, however, is provided in association with transistor 46. The addition of transistor 72 provides a measure of gain stabilization which causes circuit 70 to operate slightly more consistently for variations in ambient temperature and supply voltage.

With the possible exception of matched-silicon transistors 44 and 46, both current-sensing circuits 43 and 70 (Fig. 2A and 2B) may be advantageously formed by inexpensive, discrete elements.

In current-sensing circuit 70, PNP transistors 44, 46 and 72 preferably each have a typical beta value of 200 and a typical breakdown voltage of 60 volts, and resistors 48 and 50 preferably have values of 240 and 6.5K ohms, respectively. Additionally, a shunting capacitor 49 (shown in phantom) across resistor 48 is preferably used to filter any potential current spikes during turn-on. Typical values are 0.001 or 0.01 microfarads.

In Fig. 4, gate override circuit 26, described above in connection with Fig. 1, is shown in more detail. Considering Fig. 4, an over-current signal from over-current detector 24, typically at a 5-volt level, may be provided to the reset terminal of a reset/set latch 80, which may be conventionally formed by two CMOS NAND gates (not shown). A signal applied to the reset terminal of latch 80 will override any signal from gate control function 28 which is supplied to the set input of the reset/set latch 80 and which typically is a 5-volt signal from a microprocessor. The output of the reset/set latch

80 is then processed by a pre-driver circuit 82 to provide appropriate biasing signals for gates G₁ and G₄ of switches S₁ and S₄ (Fig. 1), respectively.

The high potential side gates G₁ and G₃ are preferably provided with a biasing voltage of about 12 volts above the supply voltage, which may be generated with a conventional voltage-doubling circuit (not shown). This is in contrast to the low potential side gates G₂ and G₄ which are preferably provided with a biasing voltage at the supply voltage level, typically 12 volts. Pre-driver circuit 82 cooperates with a counterpart pre-driver circuit (not shown) of gate override circuit 32 (Fig. 1) to provide the foregoing biasing voltages. The foregoing pre-driver circuits can be designed as illustrated to have one logic input from latch 80 control switches S₂ and S₃ and the other logic input (not shown) control the other two switches. Alternatively, the pre-driver circuits can be designed to have one logic input toggle switches S₁, S₂, or vice-versa; and to have the other logic input likewise toggle the other switches.

Pre-driver circuit 82 and its counterpart (not shown) for switches S₂ and S₃ can, further, be designed to provide delay times to the control signals on gates G₁-G₄ to insure that current is fully off in one direction through the load before causing current flow in the other direction. Alternatively, gate control functions 28 and 34 (Fig. 1), typically implemented by a microprocessor, may provide such delay times.

Fig. 5 shows a more generalized form of the invention in which a single current switch S₁ is placed on the high potential side of a load 14. The over-current detector 24, gate override circuit 26, and gate control function 28 correspond to the like-numbered parts shown in connection with the above-described power delivery circuit of the H-bridge type.

Fig. 6 shows still another embodiment of a current-sensing circuit in which all components similar to those of Fig. 2A have like identifying numerals. Fig. 6 differs from Fig. 2A in that resistor 90 is tied between the bases of transistors 44 and 46 and ground and the collector of transistor 46 goes directly to ground. The circuit of Fig. 6 has been found to experience significant variations in current ratio with changes in voltage, current, transistor beta mismatch, and temperature change. These problems are largely avoided in the circuit of Fig. 2A, particularly in response to changes in supply voltage, beta mismatch and temperature changes. The circuit of Fig. 6 demonstrates, in some respects, the principle of operation of the circuits of Figs. 2A and 2B. Although it may be satisfactory for some applications having constant operating conditions or in which significant accuracy is not required, it is not generally suited to

typical automotive applications requiring an accuracy within $\pm 3\%$ across the earlier-mentioned operating ranges. In the circuit of Fig. 6, resistor 48 may have a resistance of 1000 ohms and resistor 90 a resistance from 100K to 1 megohm.

Although the current sensing circuits which employ a plurality of matched transistors in an inverted current mirror configuration do provide certain advantages over the current sensing circuitry associated with the aforementioned U.S. patent 4,654,568, they still exhibit certain limitations when the supply voltage in the power delivery circuit varies, such that they maintain a constant current proportionality between the sense current and the load current over only a limited load current range. These limitations manifest themselves as errors in the current sensing MOSFET(s) ratio or proportionality and in the sensing circuits connected thereto. However, the circuitry of Figs. 7-12 overcomes most of those limitations.

Referring now to Figs. 7-12 depicting a further improvement of the present invention wherein like reference numerals refer to like parts.

Fig. 7 depicts the current sensing circuit of the invention in a generalized block diagram form and connected in operative association with one or more current controlling devices, and specifically current sensing switches, which are in turn connected in a power delivery circuit to a load. More particularly, the current sensing switches are part of an H-bridge switching arrangement for providing bidirectional control of the load device. More particularly still, and of significant importance to the invention, each current sensing switch to which the current sensing circuitry of the invention is connected appears in the "high", or relatively more positive, side of the power delivery circuit relative to the load device.

In Fig. 7, an H-bridge circuit 110 includes a load 14, such as a bidirectional electrical motor. The upper, or "high" side, arms of the H-bridge circuit 110 is connected to a relatively positive power supply potential, in this instance V_{BATT} which may correspond with the battery supply voltage in a vehicle. The lower, or "low" side, arms of the H-bridge circuit 110 are connected to the opposite polarity of the power supply, which in this instance is connected to ground potential. Ground potential serves as the reference potential for the power supply circuit.

Connected in the upper left and upper right arms of the H-bridge 110 are current controlling devices having a current sensing capability and specifically, current-sensing power switches S_1 and S_3 , respectively. The current sensing switches S_1 and S_3 represent the type of power carrying field effect transistor which is multi-cellular, and includes a major current carrying cellular portion and a

minor current carrying cellular portion as previously described. The current sensing MOSFETs S_1 and S_3 include a gate terminal G for control, major current-carrying terminals represented by the drain D and by the source S, a first auxiliary terminal, C. S., connected at one end to the minority of cells in the sensing MOSFET S_1 so as to provide a current generally proportional to the main device current, and a second auxiliary terminal, generally designated the Kelvin terminal, K, connected at one end to the majority of the cells of switch S_1 and substantially electrically in common with the source terminal.

Typically, the direction of rotation of motor 14 will be controlled by causing current flow therethrough in one direction or the other. Thus, for example, current sensing switch S_1 in the upper left leg and switch S_4 in the lower right leg will be caused to conduct concurrently for motor rotation in one direction. In such instance, current from the source V_{BATT} will flow via the drain terminal D of current sensing switch S_1 , and includes the major component of current supplied to the other polarity (i.e., ground potential) of the power supply via the power switch S_4 and the motor 14 from the source terminal S and the majority of cells in the current sensing switch S_1 . A current proportional to but less than, the main current at terminal S is in turn provided via the minority cells at the current sense terminal C.S. Typically, the ratio of cells or major current carrying cellular portion to minor current carrying cellular portion, and thus of currents, may be on the order of 1000:1.

To provide a signal which is proportional to the main current carried by the source terminal S, it is necessary, or at least highly preferable, that the potential at the C.S. terminal be the same as that at the source terminal S. Accordingly, an auxiliary contact designated the Kelvin contact K is electrically connected to the source terminal S and provides a signal representative of the potential at the source terminal. As will be hereinafter appreciated, the current sensing circuit associated with current sensing MOSFET S_1 endeavors to maintain the potential at the Kelvin terminal K and the current sense terminal C.S. equal to one another.

To develop the signal representative of the current carried by the current sensing switch S_1 , a current sensing circuit, generally depicted within the broken line block 120 of Fig. 7, is operatively connected with the Kelvin and the current sense terminals of current-sensing switch S_1 , and to an appropriate potential associated with the power delivery circuit. Circuit 120 provides an output signal 125 to a comparator 127 for subsequent use in a known manner.

Specifically, the signal 125 appearing from sensing circuit 120 is a voltage level representative

of the current in terminal C.S. of switch S_1 , which is in turn proportional to the main current in switch S_1 and thus normally also through the load 14. A reference voltage, V_{REF} , is selected and connected to the "+" input of comparator 127 for comparison with the current-converted to-voltage signal 125 appearing at the "-" input of that comparator. The potential of V_{REF} is selected, in conjunction with circuit 120, to be representative of some threshold value of current in the current sense MOSFET circuit which is to be detected and indicated via the output of the comparator on line 129. Thus, so long as the voltage on line 125 is less than that of V_{REF} , the current in the current sense MOSFET, and normally through the H-bridge is presumed to be less than the monitored threshold value; whereas if the voltage on line 125 exceeds the V_{REF} , the comparator 127 provides an output 129 which indicates that the current in the H-bridge, or at least through current sensing MOSFET exceeds the monitored threshold value. It will be appreciated that signal 125 could be connected to an A-to-D converter or multiple comparators so as to monitor continuous or multiple current levels.

In order for the signal 125 from current sensing circuit 120 to be as representative as possible of the current in the H-bridge, or at least through the current sense MOSFET, it is necessary that its derivation be accomplished in a manner which is not adversely impacted by excursions in the power supply potential V_{BAT} and/or by temperature excursions in the circuitry and/or by load current excursions. In this regard, the current sensing circuitry 120 of the present invention is believed to be particularly well-suited. It should be noted that another current sensing circuit, also designated 120, is associated with the Kelvin terminal K and the current sense terminal C.S. of the current sensing MOSFET S_3 in the upper right arm of the H-bridge 110. It is of identical construction to the current sensing circuit 120 associated with current sensing MOSFET S_1 .

Referring now to the current sensing circuit 120 depicted very generally in block form at the lower left in Fig. 7, there appear two serial branches BR_1 and BR_2 , each of which includes at least two semiconductor devices, such as bipolar transistors or the like in which one is used in a transimpedance mode of operation. Serial branch BR_1 is connected at one end to the current sense terminal C.S. of current sensing switch S_1 and is connected at its other end to a reference potential in the power delivery circuit, in this instance, ground potential. Similarly, serial branch BR_2 is connected at one end to the Kelvin terminal K of current sensing switch S_1 , and is connected at its other end to the same reference potential in the power delivery circuit, in this instance, ground potential.

In branch BR_1 , there are two semiconductor devices Q_1 and Q_3 connected in serial circuit. Similarly, in branch BR_2 there are two other semiconductor devices, Q_2 and Q_4 , connected in serial circuit therein. More particularly still, the semiconductor devices, which hereinafter for convenience will be referred to as transistors, are cross-connected to provide a particular bias control. Specifically, transistor Q_2 is cross-connected via lead CC_{12} to transistor Q_1 operating in the transimpedance mode to provide bias control to the latter. Similarly, transistor Q_3 is cross-connected via lead CC_{34} to transistor Q_4 operating in the transimpedance mode to provide bias control to the latter.

A sensing resistor R_s is shown in serial circuit with transistors Q_1 and Q_3 in branch BR_1 for developing the voltage signal 125 extended to comparator 127. Though the sensing resistor is shown in the generic circuit of Fig. 7 as being the only resistor depicted in the current sensing circuit 120 and further as being connected between transistor Q_3 and ground, it will be understood that other resistors might be included elsewhere in the branch circuits BR_1 and BR_2 and further, that the sensing resistor R_s might be connected between transistors Q_1 and Q_3 in branch circuit BR_1 . It also will be understood that a capacitor can be included electrically in parallel with the sense resistor R_s which will bypass potential current spikes caused by turn-on and turn-off of the current sense MOSFET.

The described branch circuits BR_1 and BR_2 serve to provide, via transistors Q_1 and Q_2 , an impedance-matching buffer, or pseudo or inverted current mirror, in the upper portion of the circuit 120 and connected to the terminals C.S. and K, whereas transistors Q_3 and Q_4 in the lower portion of circuit 20 define a more conventional current mirror. The bottom two transistors, Q_3 and Q_4 , operate in current-mirror fashion to maintain near-equal collector currents, and therefore base-emitter voltages, through the upper transistors Q_1 and Q_2 .

For a better understanding of the current sensing circuitry 120 depicted generally in Fig. 7, reference is made to several alternative, specific embodiments thereof as depicted in Figs. 8, 9, 10, 11, and 12, respectively. To emphasize any differences between those circuits, the current sensing circuit of Fig. 8 is designated 120', that of Fig. 9 is designated 120'', that of Fig. 10 is designated 120''' that of Fig. 11 is designated 120'', and that of Fig. 12 is designated 120''. On the other hand, the transistors Q_1 - Q_4 each bear the same identifying reference and will typically be the same from one circuit to the next, though some variation is contemplated within the scope of the invention. Additionally, Figs. 11 and 12 have transistors Q_5 and Q_6 . In each instance, it is important that the betas

(β) of transistors Q_1 and Q_2 be the same and the betas of transistors Q_3 and Q_4 be the same. Thus, transistors Q_1 and Q_2 are preferably two matched PNP transistors and transistors Q_3 and Q_4 are two matched NPN transistors. In some instances, it may also be desirable that the betas (β) of transistors Q_1 and Q_2 be the same as those of transistors Q_3 and Q_4 . Higher values of beta result in more accurate current mirroring between Q_1 and Q_2 and between Q_3 and Q_4 . The end result is that the base-emitter voltages of Q_1 and Q_2 , and thus the voltages at the C.S. and Kelvin terminals, will become more equal. The transistors in these exemplary embodiments are incorporated in an integrated circuit.

The sense impedance or resistance across which the sense voltage is developed, has been designated R_s in Fig. 8, R_s' in Fig. 9, R_s'' in Fig. 10, R_s''' in Fig. 11 and R_s'''' in Fig. 12. While the function of sense resistor $R_s - R_s''''$ is similar in each of those embodiments, its actual value and positioning within the circuit may vary somewhat. Accordingly, the superscripted primes have been applied for ease of identification. In each instance, the sense resistor $R_s - R_s''''$ will appear in serial circuit with the transistors Q_1 and Q_3 in branch BR_1 and which is in turn connected to the current sense terminal C.S. of current sense switch S_1 .

Referring to Fig. 8, the current sensing circuit 120' includes transistors Q_1 and Q_3 connected in serial circuit between current sense terminal C.S. and ground. It further includes transistors Q_2 and Q_4 connected in serial circuit between the Kelvin terminal and ground. Transistor Q_2 is connected in a shorted base-to-collector configuration and has its base cross-connected to the base of transistor Q_1 via cross-connection CC_{12} . Transistor Q_2 effectively provides a bias signal for controlling transistor Q_1 . Connected this way, transistor Q_2 acts like a diode, thereby regulating the base-to-emitter voltage of transistor Q_1 and thus controlling the base current of transistor Q_1 . In this configuration, transistors Q_1 and Q_2 constitute an impedance matching buffer connected to the Kelvin terminal K and current sense terminal C.S. of the sensing switch S_1 .

Transistor Q_3 is connected in a shorted base-to-collector configuration and its base is connected to the base of transistor Q_4 via cross-connection CC_{34} . The collector of transistor Q_3 is connected to collector of transistor Q_1 and the collector of transistor Q_4 is connected to the collector of transistor Q_2 . Transistor Q_3 serves to provide a bias control signal to the transistor Q_4 via the cross-connection CC_{34} . Transistors Q_3 and Q_4 operate as a current mirror to maintain near-equal collector currents, and therefore base-emitter voltages, through transistors Q_1 and Q_2 .

It can be appreciated that one can ratio the emitter areas of the transistors in BR_1 , i.e. Q_1 and Q_3 , versus the emitter areas of the transistors in BR_2 , i.e. Q_2 and Q_4 , to decrease the power dissipation in one leg of the current sensing circuit. The collector current in transistor Q_3 will not be equal but will be proportional to the collector current in transistor Q_4 by the same proportional difference in the emitter area of the two transistors. The same effect occurs for transistors Q_1 and Q_2 . The end result is that the base-emitter voltages of Q_1 and Q_2 will be equal while the power dissipation in the current sensing circuit will be decreased.

A bias resistor R_B is connected in series circuit with the transistors Q_2 and Q_4 , with one end connected to the emitter of transistor Q_4 and the other connected to ground potential. The inclusion of resistor R_B helps to minimize the power dissipation through transistor Q_4 which might otherwise become significant if high currents are being sensed and/or the transistors are contained in an integrated circuit. The sense resistor R_s is connected between the emitter of transistor Q_3 and ground in the first branch circuit. The sense voltage is provided at an output node appearing at the junction between the resistor R_s and the emitter of transistor Q_3 . The sense voltage is thus the differential voltage appearing across the sense resistor R_s . Changes in the "on-resistance" of the current sense MOSFETs have no significant affect on the stability of the sense current ratio. The sense resistor R_s is referenced to ground, which results in the sense voltage being independent of the actual potential of the supply voltage, V_{BATT} . It will be understood that the potential of V_{BATT} , which is nominally 12 volts, may be expected to vary between a potential as low as 6 volts and as high as 45 volts or more during transients. This circuit is also relatively insensitive to load current changes. For high-side drives or situations in which the current sensing circuitry is connected to a high-side switch, there is no requirement for the comparator to have a common-mode voltage near equal to the potential of the supply voltage V_{BATT} , and the voltage reference is independent of that supply voltage. Further, the sense voltage can be an order of magnitude or more larger than prior art circuits, such as in U.S. 4,654,568, such that amplification is not required.

An alternative to the current sensing circuitry of 120' of Fig. 8 is depicted in the current sensing circuitry of 120" of Fig. 9. That circuit is structured similarly to that of Fig. 8 with respect to the arrangement of the four transistors $Q_1 - Q_4$, however it omits the use of a separate biasing resistor R_B in the second branch. Instead, a sense resistor R_s'' appears not only in serial circuit with transistors Q_1 and Q_3 of the first branch, but is also shared in serial circuit with transistors Q_2 and Q_4 of the

second branch. The use of a single resistor R_S provides at least two advantages over the circuitry of Fig. 8, the first being that one less input/output (I/O) pin is needed if it is assumed that the transistors are part of an integrated circuit and the resistances are external discrete devices. Secondly, there is no dependency on current ratio due to resistor matching between R_S and R_B . Of course the value of R_S will have to be selected such that it provides the requisite sense voltage level for anticipated conditions. The tolerance of the resistor R_S continues to affect the ability to sense accurately because that sensing is actually a voltage and not the current. However, it will be appreciated that very low tolerances in R_S come at a very low cost penalty.

Referring now to the current sensing circuitry 120" in Fig. 10, there is depicted another alternative to the arrangements of Fig. 8 and Fig. 9. Relative to the current sensing circuits 120" and 120" of Figs. 8 and 9 respectively, the inverted current mirror Q_1 and Q_2 and the current mirror Q_3 and Q_4 of circuit 120" functions in a substantially similar manner. On the other hand, circuitry 120" employs a single sense resistor R_S located in the first branch in serial connection between the collector of Q_1 and the collector of Q_3 . No separate resistor is contained in the second branch with transistors Q_2 and Q_4 . Although reliance upon a single resistor R_S in current sensing circuit 120" may serve to reduce the count of resistive elements employed, it may not reduce the number of I/O pins if the transistors are part of an integrated circuit since one end of resistor R_S would have to be connected to transistor Q_3 and the other end would have to be connected to the collector of transistor Q_1 . Moreover, the omission of a resistance in the serial branch having transistors Q_2 and Q_4 may result in a greater-than-desired power dissipation through transistor Q_4 in the event of high sense currents. Still further, the positioning of sense resistor R_S between transistors Q_3 and Q_1 further introduces an offset voltage occasioned by the V_{BE} of transistor Q_3 . For that latter reason, it may be more desirable to sense the differential voltage across the sense resistor, which is more conveniently done in the embodiments of Fig. 8 and Fig. 9.

In Fig. 11 there is depicted a further refinement of the invention, in which the current sensing circuit 120" includes, in addition to the transistors Q_1 through Q_4 described above, fifth and sixth transistors Q_5 and Q_6 respectively. The base of PNP transistor Q_5 is connected to the collectors of transistors Q_2 and Q_4 . The emitter of transistor Q_5 is connected to the common-base connection CC_{12} of transistors Q_1 and Q_2 , and the collector of transistor Q_5 is connected to the reference poten-

tial. Transistor Q_5 replaces the shorted base-to-collector connection of transistor Q_2 . Likewise, the base of NPN transistor Q_6 is connected to the collectors of transistors Q_1 and Q_3 . The emitter of transistor Q_6 is connected to the common-base connection of transistors Q_3 and Q_4 , and the collector of transistor Q_6 is connected to the emitter of transistor Q_4 . Transistor Q_6 replaces the shorted base-to-collector connection of transistor Q_3 . The addition of transistors Q_5 and Q_6 in this manner results in current sensing circuit 120" being less sensitive to beta variations, and thus temperature, in transistors Q_1 through Q_4 . As in the embodiment of Fig. 9, a sense resistor R_S is connected at one end to the reference potential and at the other end to transistor Q_3 of branch 1 and to transistor Q_4 of branch 2. The sense voltage signal 25 appears at the node between resistor R_S and the emitters of transistors Q_3 and Q_4 .

In Fig. 12 there is depicted yet a further embodiment of the invention in which the current sensing circuit 120" includes fifth and sixth transistors Q_5 and Q_6 respectively, connected in an alternate configuration from that of Fig. 11. Transistors Q_1 and Q_2 and transistors Q_3 and Q_4 are cross-connected at their respective bases by CC_{12} and CC_{34} respectively as in the embodiment of Fig. 9. Similarly, the collectors of transistors Q_2 and Q_3 are shorted to their respective bases. Similarly also, the sense resistor R_S is not only in serial circuit with transistors Q_1 and Q_3 of the first branch, but is also shared in serial circuit with transistors Q_2 and Q_4 of the second branch. The sense voltage 125 is obtained at the junction node between resistor R_S and the emitters of transistors Q_3 and Q_4 . However, transistors Q_5 and Q_6 are serially connected in the second and the first branches respectively.

More particularly in Fig. 12, transistor Q_5 is of the PNP type and has its emitter connected to the collector of transistor Q_2 and its collector connected to the collector of transistor Q_4 . Transistor Q_6 is of the NPN type and has its emitter connected to the collector of transistor Q_3 and its collector connected to the collector of transistor Q_1 . The base of transistor Q_5 is connected across to the collector of transistor Q_6 in the first branch by cross-connection CC_{56} . The base of transistor Q_6 is connected across to the collector of transistor Q_5 in the second branch via cross-connection CC_{65} .

Owing to the so-called Early voltage effect, changes in the voltage across a transistor may cause a change in its beta (β). Thus, for changes in the supply voltage V_{BATT} , the voltages across the transistors operating in the transimpedance mode, i.e., Q_1 and Q_4 , will change and will affect their betas (β) relative to the betas (β) of their respective mirroring transistors Q_2 and Q_3 and thus cause

variations in the ratios. However, the addition of transistors Q_5 and Q_6 , connected as shown in Fig. 12, serves to drop most of the voltage across those two transistors, thereby minimizing voltage changes across transistors Q_1 and Q_4 and thus minimizing the undesirable Early voltage effects. This results in improved performance over the range of possible variation in the supply voltage since the voltage across transistors Q_3 and Q_4 differ by only a diode drop, regardless of supply voltage. However, circuit 120" does exhibit a slightly larger voltage drop across the active elements of each branch than do the other embodiments, which results in somewhat of a decrease in operating voltage range for a given sense current.

It should be understood that the invention is not limited to the particular embodiments shown and described herein, but that various changes and modifications may be made without departing from the spirit and scope of this novel concept as defined by the following claims. By way of example, the current sensing MOSFETs might be used as linear control devices rather than as switches; the major and minor current-carrying cellular portions of the current sensing devices might be simply a relatively large cell of greater current-carrying capacity and a smaller cell of much less capacity; the output signal 125 might be utilized or monitored in a linear manner rather than with respect only to a threshold; and the current sensing circuitry might be either in fully integrated circuit form, or it may be all or partly comprised of discrete components.

Claims

1. A current detection circuit in combination with a current controlling device in a power delivery circuit for supplying load current to a load, the current controlling device being multicellular, with a major current-carrying cellular portion and a minor current-carrying cellular portion, a first main current terminal for connection to a source of power, a gate terminal for receiving a control signal, a second main current terminal connecting the major current-carrying cellular portion, a first auxiliary terminal connected at one end to the minor current-carrying cellular portion so as to provide a current generally proportional to the main device current, and a second auxiliary terminal connected at one end to the major current-carrying cellular portion, and wherein the current detection circuit comprises:
first and second branches each for connection at one end to a respective one of said first and said second auxiliary terminals and having means for connection in common at the other end to a reference potential in the power delivery circuit;

said first branch including a first series-connected semiconductor device;

said second branch including a second series-connected semiconductor device;

5 said first semiconductor device operating in a transimpedance mode and being controlled by a bias signal;

said second semiconductor device being cross-connected with said first semiconductor device to provide the respective said bias signal thereto;

10 said first branch further including impedance means connected in series circuit therewith for providing a voltage approximately proportional to the main device current at a node at one end of said impedance means; and

15 wherein said second semiconductor is connected in said second branch in a manner providing a bias signal for controlling said first semiconductor so as to result in said voltage at said node being proportional to the main device current within a relatively small tolerance range across a relatively broad operating range.

2. The combination of claim 1 wherein said power delivery circuit is connectable to a power supply having a predetermined nominal voltage; 25 said relatively small tolerance range is within about $\pm 3\%$ of the actual main device current; and said relatively broad operating range includes variations in the supply voltage of at least $\pm 25\%$ of said nominal supply voltage, variations between 30 100 and 500 in the gains (β) of said first and second semiconductors and variations in temperature of $\pm 60^\circ\text{C}$ from an ambient of about 25°C .

3. The combination of claim 1 or 2 wherein 35 said first and second semiconductors are first and second bipolar transistors respectively and being cross-connected by having their bases connected in common.

4. The combination of claim 3 wherein said first 40 and said second bipolar transistors are PNP transistors.

5. The combination of claim 3 or 4 wherein said first and said second bipolar transistors are formed of matched silicon.

45 6. The combination of any of claims 3 to 5 wherein the base and the collector of said second bipolar transistor are shorted to one another.

7. The combination of any of claims 1 to 6 50 wherein said second branch further includes other impedance means connected in series circuit with said second semiconductor.

8. The combination of any of claims 1 to 7 further comprising current turn-off means for turning off the current controlling device via the gate terminal when the current detection circuit detects load current in excess of a predetermined level.

55 9. The combination of any of claims 1 to 8 wherein

said first branch includes first and third series-connected semiconductor devices; said second branch includes second and fourth series-connected semiconductor devices; said first and said fourth semiconductor devices operating in a transimpedance mode and each being controlled by bias signals; and said second and said third semiconductor devices being cross-connected with said first and said fourth semiconductor devices respectively to provide the respective said bias signals thereto.

10. The current sensing circuit of claim 9 wherein said first, second, third and fourth semiconductor devices comprise first, second, third and fourth transistors respectively, said first and said second transistors being one of two conductivity types and said third and said fourth transistors being the other of the two conductivity types.

11. The current sensing circuit of claim 10 wherein said first, second, third and fourth transistors are each bipolar transistors.

12. The current sensing circuit of claim 11 wherein the first main current terminal of the current controlling device is adapted to be connected to one polarity of a source of power having relatively opposite polarities, the second main current terminal of the current controlling device is adapted to be connected to one side of a load, the other side of the load being adapted to be connected to the other polarity of the source of power, and wherein both said first and said second transistors are PNP transistors and both said third and said fourth transistors are NPN transistors.

13. The current sensing circuit of claim 12 wherein said reference potential in the power delivery circuit, to which said first and second branches of said sensing circuit has said means for connection in common, is said other polarity of the source of power.

14. The current sensing circuit of any of claims 10 to 13 wherein the betas (β) of said first and said second transistors are substantially identical and the betas (β) of said third and said fourth transistors are substantially identical.

15. The current sensing circuit of any of claims 11 to 14 wherein said second and said third transistors are each connected in respective shorted base-to-collector configurations and wherein the base of said second transistor is connected to the base of said first transistor and the base of said third transistor is connected to the base of said fourth transistor.

16. The current sensing circuit of any of claims 1 to 15 wherein said impedance means in said first branch is a first resistor.

17. The current sensing circuit of any of claims 7 to 16 wherein said second branch circuit includes a respective second resistor in series circuit there-

with.

18. The current sensing circuit of any of claims 1 to 15 wherein said impedance means in said first branch comprises a resistor, said resistor further being connected in series circuit in said second branch whereby said resistor is connected in common in said first and said second branches.

19. The current sensing circuit of any of claims 12 to 18 wherein said one polarity of a source of power is relatively more positive than said other polarity of the source of power such that said current switch is connected in the relatively more positive, or high, side of the power delivery circuit relative to the load.

20. The current sensing circuit of any of claims 12 to 19 further including fifth and sixth bipolar transistors, said fifth transistor being of the same conductivity type as said first and second transistors and said sixth transistor being of the same conductivity type as said third and fourth transistors, the emitter-base junction of said fifth transistor being connected between the base and collector of said second transistor, the emitter-base junction of said sixth transistor being connected between the base and collector of said third transistor, the collector of said fifth transistor being adapted to be connected to the reference potential and the collector of said sixth transistor being adapted to be connected to said first auxiliary terminal of said current controlling device, whereby to reduce sensitivity to the betas (β) of the first, second, third and fourth transistors.

21. The current sensing circuit of any of claims 12 to 19 further including fifth and sixth bipolar transistors, said second and said third transistors each connected in respective shorted base-to-collector configurations, the fifth transistor having its emitter and collector connected in serial circuit in the second branch between said second and said fourth transistors, the sixth transistor having its emitter and collector connected in serial circuit in the first branch between said first and said third transistors, the bases of said fifth and said sixth transistors being connected to the collectors of said sixth and said fifth transistors respectively, whereby voltage drops between the emitters and collectors of the respective said fifth and sixth transistors serve to limit the voltage drops between the emitters and collectors of the respective said first and fourth transistors to thereby reduce variations in the betas (β) of the first, second, third, and fourth transistors for variations in the voltage across the power delivery circuit.

22. A power delivery circuit of the H-bridge type including:
a load leg having two end nodes and means to connect to a load;
a power means for connection to a source of

electrical power having a predetermined nominal voltage for supplying current to the load; a ground means for providing a path for returning load current to the source of electrical power; a first current path for supplying load current through the load in a first direction comprising a first high potential leg connected between the power means and a first end node of the load leg, and a first low potential leg connected between a second end node of the load leg and the ground means; and a second current path for supplying load current through the load in a second direction comprising a second high potential leg connected between the power means and the second end node of the load leg, and a second low potential leg connected between the first end node of the load leg and the ground means; the high and low potential legs each including a respective current switch, each said high potential leg current switch being multicellular with a plurality of terminals, including a first main current terminal connected to the power means, a second main current terminal connecting a majority of device cells to a respective end node of the load leg, a control terminal for controlling the switching state of the switch in response to a control signal, a first auxiliary terminal connected to one end of a minority of switch cells so as to provide a current generally proportional to the main switch current, and a second auxiliary terminal connected at one end to the majority of switch cells; the power delivery circuit further comprising first and second current detection circuits responsive to electrical conditions in the first and second high potential legs, respectively, for detection the current level in either of such legs; each current detection circuit comprising a first branch connected between the first auxiliary terminal and the ground means and including in serial circuit, a resistor providing a voltage at one end approximately proportional to the main switch current and a bias signal-controlled first bipolar transistor, and a second branch connected between the second auxiliary terminal and the ground means and including in serial circuit, a second bipolar transistor, the base of the second transistor being shorted to its collector and being connected to the base of the first transistor for providing a bias signal for the first transistor in the first branch whereby said voltage at said resistor one end is proportional to the actual main switch current within $\pm 3\%$ for variations in the source voltage in a range of at least $\pm 25\%$ of said nominal source voltage and variations between 100 and 500 in the gains (β) of said first and second transistors.

23. In an H-bridge power delivery circuit for a load, the H-bridge circuit including two upper arms

adapted to be connected to a positive supply potential and two lower arms adapted to be connected to a reference potential, a respective current sensing MOSFET in each upper arm of said H-bridge and a respective switch in each lower arm of said H-bridge, each said current sensing MOSFET comprising a multi-cellular device with a first main current terminal, a gate terminal for receiving a control signal, a second main current terminal connecting a majority of device cells, a first auxiliary terminal connected at one end to a minority of device cells so as to provide a current generally proportional to the main device current, and a second auxiliary terminal connected at one end to the majority of device cells, and an improved current sensing circuit connected to said first and said second auxiliary terminals of each of said current sensing MOSFETs and to said reference potential for providing an output signal voltage approximately proportional to the main device current, the current sensing circuit comprising first and second branches, the first branch including, in serial circuit, first and third bipolar transistors and a sense resistor, the first transistor being connected to the first auxiliary terminal of the respective current sensing MOSFET and one end of the resistor being connected to the reference potential and the other end being connected to the third transistor at a node, the second branch including, in serial circuit, second and fourth bipolar transistors, the second transistor being connected to the second auxiliary terminal of the respective current sensing MOSFET and the fourth transistor being connected to the sense resistor at said node, said first and said fourth transistors each being controlled by respective bias signals provided by cross-connection with said second and said third transistors respectively, and wherein said output signal voltage comprises the voltage appearing at said node.
